## INTRODUCTION

Childs (1971) recognized that an assumption had been incorrectly made for determinations of groundwater flow supplied by uniform rainfall over a sloping bed to transverse ditch drains. Werner (1957) and Schmid and Luthin (1964) believed that equipotential lines are vertical to the sloping bed, which they are actually perpendicular. These equipotential lines can be thought of as contour lines for the water table. So, this incorrect theory caused problems in previously derived equations. Childs (1971) modified these studies and presented a differential equation for the determination of groundwater flow, assuming streamlines were parallel to the bed slope. Childs (1971) alleged that no analytical solutions could be determined because how specific the cases for this theory were. Towner (1975) discovered that by integrating this differential equation, analytical solutions could be determined and these solutions were very similar to those of Schmid and Lutin (1964). Three analytical solutions were formed under three cases that were dependent upon bed slope, rainfall rate and hydraulic conductivity. Using these solutions for each case, the greatest vertical height to the water table mound, the location to this height and to the watershed, and the shape of the water table mound could be determined for a horizontal aquifer system. Using the integrated analytical solutions, VBA code and Newton's method, the vertical distance of the water table above the sloping bed,  $z$ , was estimated from a supplied horizontal distance measured from the upper drain,  $x$ .

## PROBLEM STATEMENT

For Towner and the research within this paper, the drainage of groundwater in equilibrium with uniform rainfall flowing down a sloping bed via equidistant, parallel ditch drains routing down the bed slope and into the impermeable bed posed as an issue (1975). The vertical distance of the water table above the sloping bed needed to be estimated given a horizontal distance measured from the upper drain. From these distances, the shape and location of the water table could be determined for a horizontal aquifer system.

## SKETCH

Figure 1 is a representation of a typical unconfined aquifer system with uniform rainfall infiltrating groundwater and draining over a bed slope. The bed slope, which is the very bottom layer of Figure 1 beneath the groundwater, will vary and is dependent upon the bed slope,  $a$ . Figure 2 is a cross section view of groundwater flowing between drains on a sloping bed. This figure helps better visualize a horizontal aquifer system and recognize parameters of the analytical solutions.

## KNOWN

The known parameters, excluding  $z$ , for the aquifer system are shown in Figure 2.  $P$  represents the uniform rainfall rate.  $H$  represents the highest point or mound on the water table and is the maximum value of  $z$  for said case. The horizontal distance measured from the upper drain is represented by  $x$ . The bed slope is given by  $a$  and the hydraulic conductivity is given by  $k$ .  $\mathcal{L}$  represents the horizontal distance to the watershed. Using these parameters, the integrated analytical solutions for each case could be put into  $x$  as a function of  $z$  and  $z$  could be determined for any given value of  $x$ .

## UNKNOWN

The main goal of this research was to manipulate each solution for each case using a supplied value of  $x$  to determine the associated value of  $z$ . Newton's method was used in order to estimate the value of  $z$  as  $x$  approached zero.

## ANALYTICAL SOLUTIONS

As previously stated, it was believed that no analytical solutions could be determined, but this was incorrect. *Towner* (1975) calculated analytical solutions by integrating differential equations derived by *Childs* (1971), which this research stemmed from various ideas presented from previous researchers. These solutions determined from integration were for the case of ditches and uniform rainfall. *Towner* developed three solutions for three different cases, which were dependent upon a relationship between the known values. Using these solutions, the greatest vertical height to the water table mound, the location to this height and to the watershed, and the shape of the water table mound could all be determined. Furthermore, by setting the analytical solutions for each case to zero,  $x$  became a function of  $z$  and the critical points were found that determined a corresponding  $z$ .

## VBA CODING METHODOLOGY

A module is used in developer within Microsoft Word to code functions. Within these functions, there are parameter names that define variables. Table 1 shows the variables and their parameter names used and seen throughout this VBA code. The description explains what the specific parameter is used for or relates to.

TABLE 1. VBA PARAMETERS AND FUNCTION NAMES USED FOR TOWNER VARIABLES AND DESCRIPTIONS OF EACH

Description	Variable	VBA Parameter
Bed slope	a	a
Rainfall rate	p	p
Hydraulic conductivity	k	k
Horizontal distance from upper drain	x	x
Vertical distance of water table above sloping bed	z	z
Horizontal distance between the drains	L	L
Horizontal distance to the watershed	$\mathcal{L}$	curvyL
Value differentiating between case 1, 2, or 3	A	capA
Relationship between x and $\mathcal{L}$	v	vValue
Defining value for all cases	W	capW
Defining value for case 1	m	mValue
Defining value for case 1	u <sub>0</sub>	uSub0
Defining value for case 1	u <sub>H</sub>	uSubH
Height of the mound of water for case 1	H <sub>1</sub>	capH1
Defining value for case 1	u	uValue
Horizontal distance to mound for case 1	X <sub>1</sub>	capX1
Height of the mound of water for case 2	H <sub>2</sub>	capH2
Horizontal distance to mound for case 2	X <sub>2</sub>	capX2
Defining value for case 3	W <sub>1</sub>	capW1

In Table 2, there are a few basic VBA symbols used for certain operations in functions and code.

TABLE 2. HELPFUL VBA OPERATIONS AND SYMBOLS

Operation	Symbol
Greater than	>
Less than	<
Greater than or equal to	>=
Less than or	<=
Equal to	=
Not equal to	<>
Natural log, ln	Log
Defines a comment describing code/function	'comment
Defines a string value is being used	""
Defines function and/or parameter data type	As Double (or String)

The operational math terms like “greater than” or “equal to” are very helpful to know for IF-THEN-ELSE statements. Using the symbols can help simplify code that could be in multiple functions and make them into single functions. The natural log was used quite often within this code and needed to be defined so there would be no confusion when calling the natural log function in the module. Comments can be helpful and describe what a certain function is doing or just clear something up within the code that is not obvious. A comment should at least be used before each function and more than one comment can be used. Where a comment is located in the function does not affect anything. Finally, there are two data types in code, “string” and “double”. Double defines a number and using the identifier character “#” after a number forces it to become a double data type. String defines text and words. Functions and parameters can be forced as a number or text value.

### ERROR HANDLING

Error handling has been done through out the computation of each function. Some of these error handlers used notified the user when null values were put in, a parameter was zero that could not be, or when a number for a certain variable needs to be changed. Also, basic error handlers have been put used in case of general errors arising. When these errors happen, the error handlers give the user an error number and description to better diagnose the issue. The algorithm for an error handler returning an error number and description is as follows:

1. Put “On Error” statement or IF statement for an error after function parameters and name are defined and before the function equation or IF-THEN-ELSE statements.

On Error GoTo ErrorHandlerParameterIssue

OR

If parameter..Then GoTo ErrorHandlerParameterIssue

2. “Exit Function” and put in error handler(s) name before “End Function”

3. Type in message wanted to be returned on error and if necessary, make the error handler return number and description. Also, a certain string or double can be set to return in the spreadsheet for the function value on error.

Exit Function

```
ErrorHandlerParameterIssue:
  MsgBox "message" & vbCrLf & "Error" & Err.Number &
  ":" & Err.Description
  FunctionName = "string" or Number
Exit Function
```

End Function

### NEWTON'S METHOD

Newton's method was used to estimate a value of  $z$  from a supplied  $x$  value. By finding the zeroes or critical points of the analytical solutions for each case, a value of  $z$  was estimated from a specific  $x$  value. Each solution was set to zero by moving all terms in the function to one side. A loop function was used to guess values of  $z$ . This was done by finding the slope at a certain point of the function, which gave a corresponding  $x$  and  $z$  value. The loop continued until the value of  $x$  was approximately zero, hence, giving the appropriate value of  $z$ . The equation defining Newton's method in terms of this case of estimating  $z$  is as follows:

$$z_{n+1} = z_n - \frac{f(z_n)}{f'(z_n)}$$

In this equation,  $z_n$  is the first initial guess the loop starts at. The function or analytical solutions with the estimated  $z$  value is represented by  $f(z_n)$  and the derivative of that function, which represents the slope of the function at that point, is represented by  $f'(z_n)$ . To estimate with Newton's method and use a loop, a step size was given and this was the deviation from the original guess each additional guess would follow until it reached a critical point. Also, a number of guesses were given for the count used in the loop, along with a tolerance that governed if the function value was close enough to zero. The derivative of the function in this case was found by the following equation:

$$f'(z_n) = \frac{f(\text{constants}, z_n + \text{stepsize}) - f(\text{constants}, z_n)}{\text{stepsize}}$$

Here, the constants are values like  $A$ ,  $a$ ,  $p$ ,  $k$  and so on. These values do not change based off of the given  $x$  value and therefore, are considered constants. Using these functions and tolerance in a loop, allowed for the approximation of  $z$ .

### EQUATION SELECTION

Towner (1975) uses and manipulates Childs' notation of a revised differential equation correction Werner (1975) and Schmid and Luthin (1964) to come up with the following relationship.

$$\int \frac{W}{W^2 - AW + \left(\frac{p}{k}\right)} dW = - \int \frac{dv}{v}$$

This relationship was integrated from the following function, which is Equation 1 in Towner (1975):

$$\frac{dz}{dx} = \frac{akz - p(x - \mathcal{L})(1 + a^2)}{kz - p(x - \mathcal{L})a}$$

In this integration,  $v$  and  $W$  are defined where:

$$v = x - \mathcal{L}$$

$$W = \frac{z}{v} - a\left(\frac{p}{k}\right)$$

The following VBA script in Figures 3 and 4 represents the two functions calculating  $W$  and  $v$ .

```

TownerModel-27APR16.xlsm - Module1 (Code)
(General) Case3
'Calculating the value of W
Function capW(z As Double, vValue As Double, a, p, k)
    If vValue = 0 Or k = 0 Then GoTo ErrorHandlerDivideByZero
    capW = (z / vValue) - a * (p / k)
    Exit Function

ErrorHandlerDivideByZero:
    MsgBox "An error occurred calculating W because v or k are zero" & vbCrLf & "Error " & Err.Number & ": " & Err.Description
    Exit Function

End Function

```

FIGURE 3. FUNCTION USED TO DETERMINE W

```

TownerModel-27APR16.xlsm - Module1 (Code)
(General) Case3
'Calculating the value of v
Function vValue(x As Double, curvyL As Double) As Double
    If x = curvyL Then GoTo ErrorHandlerVValue
    vValue = x - curvyL
    Exit Function

ErrorHandlerVValue:
    MsgBox "x cannot equal curvy L" & vbCrLf & "Error " & Err.Number & ": " & Err.Description
    Exit Function

End Function

```

FIGURE 4. FUNCTION USED TO DETERMINE v

Towner (1975) reduces the hydraulics to three cases depending on the value of the variable  $A$  and the rainfall rate and hydraulic conductivity within the groundwater portion. After integrating Equation 1 in Towner (1975), it was seen that the

analytical solution depends on the relationship between  $A^2$  being greater than, less than, or equal to  $4*(p/k)$ . On page 144 of Towner, A is defined as:

$$A = a \left[ 1 - \frac{p}{k} \right]$$

The VBA script calculates the value of A in the code fragment seen in Figure 5.

```

ProjectBeginningCode.xlsm - Module1 (Code)
(General) capA
'Calculating A to determine if we use Case 1, 2 or 3
'Declare parameters as Variant type (without an explicit type) so that they can have empty values
'Since Doubles automatically get set to 0
Function capA(a, p, k)

    If IsEmpty(a) Or IsEmpty(p) Or IsEmpty(k) Then GoTo ErrorHandlerEmpty
    If k = 0 Then GoTo ErrorHandlerDivideByZero
    On Error GoTo ErrorHandlerCapA
    capA = a * (1# - (p / k))
    Exit Function

ErrorHandlerEmpty:
    MsgBox "Must provide values for parameters a, p and k"
    capA = "ERROR"
    Exit Function

ErrorHandlerDivideByZero:
    MsgBox "k cannot be zero when calculating A"
    capA = "ERROR"
    Exit Function

ErrorHandlerCapA:
    MsgBox "An error occurred calculating A" & vbCrLf & "Error " & Err.Number & ": " & Err.Description
    Exit Function

End Function
    
```

FIGURE 5. FUNCTION USED TO DETERMINE VALUE OF A

The VBA script makes the selection of the equation, or case, to use using the code fragment shown in Figure 2. Case 1 was defined by  $A^2 < 4(p/k)$ . Case 2 was defined by  $A^2 = 4(p/k)$ . Case 3 was defined by  $A^2 > 4(p/k)$ .

```

TownerModel-03MAR16.xlsm - Module1
(General) capX3
'Determining which case parameters fall into
Function ChooseCase(capA As Double, p As Double, k As Double) As String

    On Error GoTo ErrorHandlerChooseCase
    If capA ^ 2 < 4# * (p / k) Then
        ChooseCase = "Case 1"
    ElseIf capA ^ 2 = 4# * (p / k) Then
        ChooseCase = "Case 2"
    ElseIf capA ^ 2 > 4# * (p / k) Then
        ChooseCase = "Case 3"
    End If
    Exit Function

ErrorHandlerChooseCase:
    MsgBox "An error occurred choosing case" & vbCrLf & "Error " & Err.Number & ": " & Err.Description
    Exit Function

End Function
    
```

FIGURE 6. SELECTING WHICH EQUATION (CASE) TO USE BASED OFF OF CALCULATED A VALUE

In order to estimate a value of z for all three cases, values for  $a$ ,  $p$ , and  $k$  that fell below each case were determined. Values could easily be found for Cases 1 and 3, but Case 2 was trickier. Using algebra, it was found that Case 2 solutions governed

when  $a$  was equal to -2.4,  $p$  was equal to 9, and  $k$  was equal to 4. Furthermore, Figure 6 shows a good example of an IF-THEN-ELSE statement and the algorithm is as follows:

1. Code If statement after function name and parameters are defined and after error handlers. Operational math terms can be used to compare numbers or parameters or strings can be used to define the if statement.

```
If Parameter1 < (>, =, <>, <=, >=) Parameter2 Then  
    Function = Double or "String"
```

2. Code ElseIf statement if additional conditions can be applied

```
ElseIf Parameter1 > (>, =, <>, <=, >=) Parameter2 Then  
    Function = Double or "String"
```

3. Code Else statement to define outcome if no previous conditions apply and end function with End If statement. To ensure no error, input Exit Function statement after End If.

```
Else  
    Function = Double or "String"  
End If  
Exit Function  
End Function
```

## METHODS TESTING

### CASE 1

Throughout each case, different variables had to be found to solve the analytical solution. For Case 1, functions for  $m$ ,  $u$ , and  $u_0$  had to be written to determine the solutions. The value of  $m$  was calculated using the code fragment in Figure 7. Using an IF-THEN-ELSE statement, a string of "N/A" will be returned when the case does not fall under Case 1. Throughout the code fragments, IF-THEN-ELSE statements were used to define a function value as "N/A" when the case was not met. This allowed for a cleaner looking spreadsheet interface and ensured no errors would return in a cell if the function was not applicable to the specific case.

```

TownerModel-03MAR16.xlsm - Module1 (Code)
(General) capX3
'Calculating value of m for Case 1
Function mValue(p, k, capA)

    On Error GoTo ErrorHandlerM
    If capA ^ 2 < 4# * (p / k) Then
        mValue = ((p / k) - ((capA ^ 2) / 4#)) ^ (-1 / 2)
    Else: mValue = "N/A"
    End If
    Exit Function

ErrorHandlerM:
    MsgBox "An error occurred calculating m " & vbCrLf & "Error " & Err.Number & ": " & Err.Description
    Exit Function

End Function

```

FIGURE 7. FUNCTION USED TO DETERMINE M FOR CASE 1

Figure 8 shows Equation 4 from Towner (1975).

$$\ln \left( \frac{H}{L - \mathcal{L}} \right)^2 = \ln \left[ \left( \frac{1 + a^2}{a} \right)^2 \left( \frac{p}{k} \right)^2 \left( \frac{u_0^2 + 1}{u_H^2 + 1} \right) \right] + Am(\tan^{-1} u_0 - \tan^{-1} u_H) \quad (4)$$

where

$$u_0 = -m \left( \frac{p}{k} a + \frac{A}{2} \right)$$

and

$$u_H = m \left( \frac{p}{ka} - \frac{A}{2} \right)$$

FIGURE 8. EQUATION 4 IN TOWNER USED TO DETERMINE THE MOUND, H, FOR CASE 1

The first function in this figure represents the function to determine the maximum value of  $z$  for Case 1. To determine the point of the mound,  $H$ , a function had to be made for  $u_H$ . The entire right hand side of Towner Equation 4 is comprised of known values; that is it is a constant. So, in the code, the right hand side is evaluated and then the following algebraic and logarithmic transformations are used to compute a value for  $H$ :

$$\ln \left( \frac{H}{L - \mathcal{L}} \right)^2 = \text{constant}$$

$$\ln \left( \frac{H}{L - \mathcal{L}} \right) = \text{constant}^{\frac{1}{2}}$$

$$\frac{H}{L - \mathcal{L}} = \exp\left(\text{constant}^{\frac{1}{2}}\right)$$

$$H = (L - \mathcal{L})\exp\left(\text{constant}^{\frac{1}{2}}\right)$$

These operations are shown in the code fragment in Figure 11.

The values  $u_0$  and  $u_H$  were computed using the code fragment in Figures 9 and 10.  $u_0$  and  $u_H$  returned a value of N/A when the case did not fall under Case1.

```

'Calculating uSub0 to solve for H for case 1
Function uSub0(mValue, p, k, a, capA)

    If k = 0 Then GoTo ErrorHandlerDivideByZero
    If mValue = "N/A" Then
        uSub0 = "N/A"
    Else
        uSub0 = (-mValue) * (((p / k) * a) + (capA / 2#))
    End If
    Exit Function

ErrorHandlerDivideByZero:
    MsgBox "k cannot be zero when calculating uSub0"
    uSub0 = "ERROR"
    Exit Function

End Function

```

        capH1 = "N/A"
    Else
        capH1 = (L - curvyL) * Exp(((Log(((1# + a ^ 2) / a) ^ 2) * ((p / k) ^ 2) * ((uSub0 ^ 2 + 1#) / (uSubH ^ 2 + 1#))) + (capA * m) * (Atn(uSub0) - Atn(uSubH)))) ^ (1 / 2))
    End If
    Exit Function

ErrorHandlerDivideByZero:
    MsgBox "k cannot be zero when calculating H1"
    capH1 = "ERROR"
    Exit Function

End Function

```

FIGURE 11. FUNCTION USED TO DETERMINE MAXIMUM H FOR CASE 3

By putting  $\frac{dz}{dz} = 0$ , the formula for  $x$ , the distance which the maximum H occurs, for Case 1 can be obtained. The maximum at which the mound occurs on the sloping bed allows for the shape of the mound to be better understood and this program. Equation 7 in Towner seen below was used to find the value of  $x$  (1975):

$$X = \mathcal{L} + \left(\frac{k}{p}\right) * \left(\frac{a}{1 + a^2}\right) * H$$

Figure 12 shows the code fragment for this function and Figure 12 shows the code fragment for the determination of  $u$ .

```

        Exit Function
    End If
    dfdxfd = (Case1(mValue, Zguess + stepsize, x, curvyL, p, k, a, capA, capH1, vValue) - Case1(mValue, Zguess, x, curvyL, p, k, a, capA, capH1, vValue)) / stepsize
    Zguess = Zguess - Case1(mValue, Zguess, x, curvyL, p, k, a, capA, capH1, vValue) / dfdxfd
Next Count
    NewtonCase1 = Zguess
End If
Exit Function
End Function

```

FIGURE 15. LOOP FUNCTION ESTIMATING Z WITH NEWTON'S METHOD FOR CASE 1 USING A SUPPLIED X VALUE

In order to do a loop function, and in this case Newton's method estimation, the algorithm is as follows:

1. Write the function name, which ultimately will return the estimated value of z, and the parameters needed for the estimation and for the analytical function.
 

```
Function EstimationValue(stepsize, tolerance, HowMany, Constants, Guess)
```
2. Code the Count statement and specify test1. Make sure when calling function that parameters are in same order from original function.
 

```
For Count = 1 to HowMany
    test1 = Function(Constants, Guess)
```
3. Create an IF statement that checks if the absolute value of the current guess at the specified count is smaller than the tolerance.
 

```
If (Abs(test1) < tolerance) Then
    EstimationValue = Guess
    Exit Function
End If
```
4. If the current guess is not smaller than the guess, Newton's method equations are used. The derivative first needs to be found for the function and then the new guess is found.
 

```
dfdxfd = ((Function(Constants, Guess+stepsize)-
(Function(Constants, Guess)))/stepsize
Guess = Guess - (Function(Constants, Guess)/dfdxfd)
```
5. Finally, using the new guess, the function goes to the next count, loops back to the beginning and checks if the new guess is below the tolerance.

```

Next Count
  EstimationValue = Guess
End If
Exit Function
End Function

```

## CASE 2

If the case falls into Case 2, a new H had to be manipulated and calculated for. Equation 8 on page 145 of Towner (1975) needed to be solved for H. To do this, both sides of the equation were multiplied by L. You can see this manipulation for the H for case 2 below:

$$\frac{H}{L} = -(1 + a^2) * \left(\frac{p}{k}\right) * \left(\frac{aA + 2}{A - 2a}\right) * \exp\left(\frac{2A * (1 + a^2)}{(A - 2a) * (Aa + 2)}\right)$$

$$H = -L * (1 + a^2) * \left(\frac{p}{k}\right) * \left(\frac{aA + 2}{A - 2a}\right) * \exp\left(\frac{2A * (1 + a^2)}{(A - 2a) * (Aa + 2)}\right)$$

Now, with height of the mound found for Case 2, the location x can be found. The equation is the same as before for Case 1 but instead  $\mathcal{L}$  is equal to zero. This results in the equation following:

$$X = \left(\frac{k}{p}\right) * \left(\frac{a}{1 + a^2}\right) * H$$

The following VBA scripts in Figure 16 and 17 represent the functions to find H and x for Case 2.

```

TownerModel-27APR16.xlsm - Module1 (Code)
(General) Case3
'Calculating H for Case 2
Function capH2(L, a, p, k, capA)
    If capA ^ 2 = 4# * (p / k) Then
        capH2 = -L * (1# + (a ^ 2)) * (p / k) * (((a * capA) + 2#) / (capA - (2# * a))) * Exp(((2# * capA) * (1# + (a ^ 2))) / ((capA - (2# * a)) * ((capA * a) + 2#)))
    Else
        capH2 = "N/A"
    End If
End Function

```

FIGURE 16. FUNCTION USED TO DETERMINE MAXIMUM H FOR CASE 2

```

TownerModel-27APR16.xlsm - Module1 (Code)
(General) Case3
'Calculating capX2 at maximum H for Case 2, curvyL=0
Function capX2(k, p, a, capH2)
    If capH2 = "N/A" Then
        capX2 = "N/A"
    Else
        capX2 = (k / p) * (a / (1# + (a ^ 2))) * capH2
    End If
End Function

```

FIGURE 17. FUNCTION USED TO DETERMINE X AT MAXIMUM H FOR CASE 2

Figure 18 shows the analytical function for Case 2 represented by Equation 9 of Towner (1975). Figure 19 shows the Newton estimation of z for Case 2.

```
"Equation 9 in Towner, this function used to get z from supplied x under Case 2
Function Case2(capA, a, p, k, x, L, Zguess, vValue)

If (capA)^2 = 4 * (p / k) Then
  Case2 = ((Log(-(((Zguess / vValue) - (a * (p / k))) - (capA / 2#)) / (a * (p / k) + (capA / 2)))) ^ 2) - ((capA * (((Zguess / vValue) - (a * (p / k))) + (a * (p / k))) / (a * (p / k) + (capA / 2#))) * (((Zguess / vValue) - (a * (p / k))) - (capA / 2#))) + ((Log(x / L)) ^ 2)
Else
  Case2 = "N/A"
End If
End Function
```

If ChooseCase <> "Case 2" Then
  NewtonCase2 = "N/A"
Else
  For Count = 1 To HowMany
    test1 = Case2(capA, a, p, k, x, L, Zguess, vValue)
    If (Abs(test1) < tolerance) Then
      NewtonCase2 = Zguess
      Exit Function
    End If
    dfdxfd = (Case2(capA, a, p, k, x, L, Zguess + stepsize, vValue) - Case2(capA, a, p, k, x, L, Zguess, vValue)) / stepsize
    Zguess = Zguess - Case2(capA, a, p, k, x, L, Zguess, vValue) / dfdxfd
  Next Count
  NewtonCase2 = Zguess
End If
Exit Function
End Function
```

FIGURE 19. LOOP FUNCTION ESTIMATING Z WITH NEWTON'S METHOD FOR CASE 2 USING A SUPPLIED X VALUE

### CASE 3

The final case is where  $A^2 > 4(p/k)$ . First, the values of  $W_1$  and  $W_2$  were needed in order to complete the relationship of Equation 11 in Towner (1975):

$$\frac{W_1}{W_1 - W_2} * \ln \left( z - x \left( W_1 + a \left( \frac{p}{k} \right) \right) \right)^2 - \frac{W_2}{W_1 - W_2} * \ln \left( z - x \left( W_2 + a \left( \frac{p}{k} \right) \right) \right)^2 = C_4$$

Where,

$$W_1 = \frac{A}{2} + \left( \frac{A^2}{4} - \frac{p}{k} \right)^{1/2}$$

$$W_2 = \frac{A}{2} - \left( \frac{A^2}{4} - \frac{p}{k} \right)^{1/2}$$

$$C_4 = \frac{W_1}{W_1 - W_2} \ln \left( H \left( \frac{1}{1 + a^2} - W_1 \left( \frac{a}{1 + a^2} \right) \left( \frac{k}{p} \right) \right) \right)^2 - \frac{W_2}{W_1 - W_2} \ln \left( H \left( \frac{1}{1 + a^2} - W_2 \left( \frac{a}{1 + a^2} \right) \left( \frac{k}{p} \right) \right) \right)^2$$

The VBA script of  $W_1$  and  $W_2$  is seen in Figures 20 and 21.

```

TowerModel-27APR16.xlsm - Module1 (Code)
(General) Case3
'Calculating capW1 for Case 3
Function capW1(capA, p, k)
    If capA ^ 2 > 4# * (p / k) Then
        capW1 = (capA / 2#) + (((capA ^ 2) / 4#) - (p / k)) ^ (1 / 2)
    Else
        capW1 = "N/A"
    End If
End Function

```

FIGURE 20. FUNCTION USED TO DETERMINE  $W_1$  TO DEFINE  $C_4$  FOR CASE 3

```

TowerModel-27APR16.xlsm - Module1 (Code)
(General) Case3
'Calculating capW2 for Case 3
Function capW2(capA, p, k)
    If capA ^ 2 > 4# * (p / k) Then
        capW2 = (capA / 2#) - (((capA ^ 2) / 4#) - (p / k)) ^ (1 / 2)
    Else
        capW2 = "N/A"
    End If
End Function

```

FIGURE 21. FUNCTION USED TO DETERMINE  $W_2$  TO DEFINE  $C_4$  FOR CASE 3

By manipulating this  $C_4$  relationship with  $W_1$  and  $W_2$  and putting  $z$  equal to zero at  $x$  equal to  $L$ , a relationship for  $H$  for case 3 was determined. Below the manipulation for  $H$  for Case 3 can be seen.

$$H = L * \left( \frac{\left( \frac{1}{1+a^2} \right) - W_2 \left( \frac{a}{1+a^2} \right) \left( \frac{k}{p} \right)}{a \left( \frac{p}{k} \right) + W_2} \right)^{W_2/(W_1-W_2)}$$

$$* \left( \left( \frac{\left( \frac{1}{1+a^2} \right) - W_1 \left( \frac{a}{1+a^2} \right) \left( \frac{k}{p} \right)}{a \left( \frac{p}{k} \right) + W_1} \right)^{W_1/(W_1-W_2)} \right)^{-1}$$

Again,  $\mathcal{L}$  is equal to zero for Case 3 as it was for Case 2. So the same equation used to find  $x$  in case 2 was used. Figures 22 and 23 shows the code fragment used to determine  $H$  and  $x$  for Case 3.

```
'Calculating H for Case 3
Function capH3(L, a, capW2, k, p, capW1)

If capW1 = "N/A" And capW2 = "N/A" Then
    capH3 = "N/A"
Else
    capH3 = L * (((1# / (1# + (a ^ 2))) - (capW2 * (k / p) * (a / (1# + (a ^ 2)))) / ((a * (p / k)) + capW2)) ^ (capW2 / (capW1 - capW2))) * (((1# / (1# + (a ^ 2))) - (capW1 * (k / p) * (a / (1# + (a ^ 2)))) / ((a * (p / k)) + capW1)) ^ (capW1 / (capW1 - capW2))) ^ (-1)
End If
End Function
```

FIGURE 22. FUNCTION USED TO DETERMINE MAXIMUM H FOR CASE 3

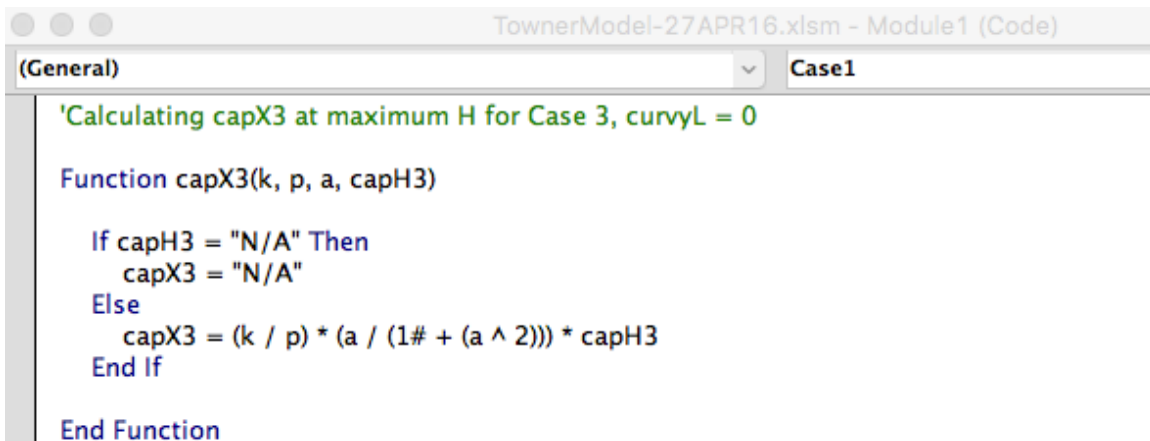

FIGURE 23. FUNCTION USED TO DETERMINE X AT MAXIMUM H FOR CASE 3

In order to use Newton's method for the analytical solution in Case 3,  $C_4$  needed to be determined. Figure 24 shows the code fragment for the  $C_4$  function.

```
'Calculating capC4 for case 3
Function capC4(capA, capW1, capW2, capH3, a, k, p)

If capA ^ 2 > 4# * (p / k) Then
    capC4 = ((capW1 / (capW1 - capW2)) * (Log((capH3 * ((1 / (1 + (a ^ 2))) - (capW1 * (a / (1 + (a ^ 2))) * (k / p)))) ^ 2) - ((capW2 / (capW1 - capW2)) * (Log((capH3 * ((1 / (1 + (a ^ 2))) - (capW2 * (a / (1 + (a ^ 2))) * (k / p)))) ^ 2)))
Else
    capC4 = "N/A"
End If
```

FIGURE 24. FUNCTION USED TO DETERMINE  $C_4$

Figure 25 represents the analytical function for Case 3 taken from Equation 11 in Towner (1975). Figure 26 shows the loop function estimating  $z$  for Case 3 using Newton's method.

```

TownerModel-27APR16.xlsm - Module1 (Code)
(General) Case3
'Equation 11 in Towner, this function used to get z from supplied x under Case 2
Function Case3(capW1, capW2, Zguess, x, a, p, k, capC4, capA)
On Error GoTo ErrorHandlerNaturalLogOfZero
If (capA) ^ 2 > 4 * (p / k) Then
Case3 = ((capW1 / (capW1 - capW2)) * ((Log((Zguess - x) * (capW1 + (a * (p / k)))) ^ 2)) - ((capW2 / (capW1 - capW2)) * ((Log((Zguess - x) * (capW2 + (a * (p / k)))) ^ 2)) - capC4)
Else
Case3 = "N/A"
End If
Exit Function

ErrorHandlerNaturalLogOfZero:
MsgBox "Guess of z for Case 3 needs to be greater than one"
Case3 = "ERROR"
Exit Function
End Function

```

FIGURE 25. FUNCTION OF EQUATION 11 IN TOWNER USED TO GET x AS A FUNCTION OF z FOR CASE 3

```

TownerModel-27APR16.xlsm - Module1 (Code)
(General) Case3
'Estimating z using Newton's Method for Case 3 given a variable of x
Function NewtonCase3(stepsize, tolerance, HowMany, Zguess, capW1, capW2, x, a, p, k, capC4, capA, ChooseCase)

If ChooseCase <> "Case 3" Then
NewtonCase3 = "N/A"

Else

For Count = 1 To HowMany
test1 = Case3(capW1, capW2, Zguess, x, a, p, k, capC4, capA)
If (Abs(test1) < tolerance) Then
NewtonCase3 = Zguess
Exit Function
End If
dfdxfd = (Case3(capW1, capW2, Zguess + stepsize, x, a, p, k, capC4, capA) - Case3(capW1, capW2, Zguess, x, a, p, k, capC4, capA)) / stepsize
Zguess = Zguess - Case3(capW1, capW2, Zguess, x, a, p, k, capC4, capA) / dfdxfd
Next Count
NewtonCase3 = Zguess
End If
Exit Function
End Function

```

FIGURE 26. LOOP FUNCTION ESTIMATING z WITH NEWTON'S METHOD FOR CASE 2 USING A SUPPLIED x VALUE

Lastly, Figure 27 shows the code fragment used to clean up the spreadsheet interface. This simply made the original input box for z equal to the estimated z value for whichever case was governing.

```

TownerModel-27APR16.xlsm - Module1 (Code)
(General) Case3
'Changing z in input values to estimated z from whichever Newton case is applicable
Function zEstimated(ChooseCase, NewtonCase1, NewtonCase2, NewtonCase3)

If ChooseCase = "Case 1" Then
zEstimated = NewtonCase1
Elseif ChooseCase = "Case 2" Then
zEstimated = NewtonCase2
Elseif ChooseCase = "Case 3" Then
zEstimated = NewtonCase3
End If
Exit Function
End Function

```
